

=> Spring MVC :-

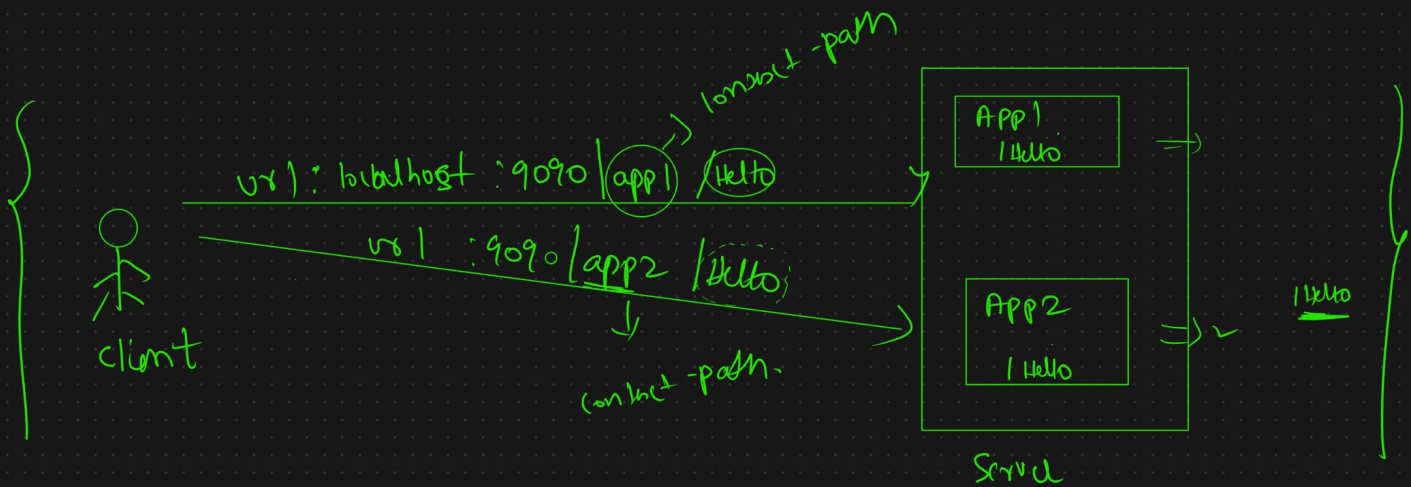

=> 1

- ==> Multiple Controllers can be created in one Web App.
- ==> In One Controller we can have multiple Controller methods
- ==> Every Controller can map class level URL pattern
- ==> We can map method level url pattern for every Controller methods
- ==> All methods url pattern must be unique

==> When We run the Spring boot app then it will be deployed in Embedded Server Container which is Apache Tomcat.

==> If we run the Spring boot web app then embedded server will start and once we stop the application then server also will be stopped

==> In embedded server container one application will be deployed as for ever new application it will have its own embedded server.

==> Spring boot web app will be deployed in embedded container in 8080 port number by default however if we have oracle db in our system we need to change port number by adding server.port property in application.properties file or even other wise to run the app in diff port num we can add server.port in our properties file.

==> Default context path for spring boot web app is empty. However we can add the context path of our app by adding property server.servlet.context-path=/AppName

Sending Data from Controller to View / UI :

- ==> We can create ModelAndView and Add model data , logical view name and return that MAV object to View/UI
- ==> We can have only Model object and add model data into it and return only logical view name;
- ==> We can add model data in the form of Map and return logical view name
- ==> We can add model data in map and we can return Map also
- ==> We add model data in Model object and Map both in key value pair
- ==> We can get the model data in view file with the help of key

Note : refer to project SpringMVCGreetMe to map above given points
