

RESTFul services ==> Spring Rest (Spring MVC)

API Development

API ==> (Core Java, Adv Java, Frameworks Spring, Hibernate) Jar==> Collection of .class files

Rest API==> Developing RestControllers having diff methods for various http method to establish cross communication between two applications (interoperability) ==> Generating endpoints (Json or XML supported format communication between multiple applications)

As a springboot developer we use @RestController to develop API. @RestController per 1 module

API Documentation

=====

When ever we develop Java app we maintain doc/info about code or app

- a) Separate Text doc
- b) Using Tool (java doc tools) , comments before code

Whenever we develop Rest api's as Spring boot developer for the documentation of the apis we have develop usually we use Swagger Api, OpenAPI

But usually Spring Boot developers use Swagger for API Documentation

==> Swagger API

==> It is an open source thirdparty library to provide Responsive API documentation for RestController and its methods

=> For All RestControllers of the project we can create API documentation from Single place while working swagger api

=> Responsive Documentation means not only we get docs about API and its methods(EndPoints) we can test immediately by providing inputs and getting outputs.

=> If this is used POSTMAN tool is not needed seperately and it is also useful to provide documentation based TestingEnvironment.

Swagger Documents provides following details

- a) API Info(licence, company , titile)
- b) End points
- c) Model class info

Steps to work with Swagger API

=====

- 1) RestAPI project to should be there(API should be ready)
- 2) Add the following jar/dependencies in pom.xml
 - a. Springfox-swagger2
 - b. springfox-swagger-ui

- 3) Develop a Configuration class enabling Swagger API

==> create a Docket object having following info

- a) Documentation type

- b) Specifying the base package of restcontroller
- c) request path info
- d) Other info about apis (License, company)
